ABSTRACT:

Breastfeeding is widely recognized as the optimal method of infant feeding, offering significant nutritional, immunological, developmental, and health benefits for both infants and mothers. Despite its advantages, breastfeeding success is often affected by challenges related to positioning, attachment, and maternal comfort, which can lead to poor milk transfer, breastfeeding complications, and early cessation. This literature review aimed to examine and synthesize existing evidence on various breastfeeding methods and their effectiveness in promoting successful breastfeeding outcomes. A narrative literature review design was adopted. Relevant studies were retrieved from electronic databases, including pubmed, google scholar, cochrane Library, and Scisearch, along with guidelines from the world health organization and United Nations Children's Fund. Peer-reviewed articles, systematic reviews, meta-analyses, randomized controlled trials, observational studies, and clinical guidelines published in English were included. The literature was analyzed thematically, focusing on different breastfeeding positions, factors influencing position selection, and their impact on maternal and infant outcomes. Findings indicate that breastfeeding success is strongly influenced by proper positioning and effective attachment, which facilitate efficient milk transfer, reduce complications, and enhance maternal comfort. Evidence suggests that no single breastfeeding position is universally superior; rather, effectiveness depends on maternal anatomy, infant developmental stage, mode of delivery, and clinical conditions. Positions such as the cross-cradle and football hold are particularly beneficial during early breastfeeding initiation, while side-lying and laid-back breastfeeding improve maternal comfort and recovery. Upright and specialized positions are useful in selected clinical situations, including reflux or prematurity. The review also highlights the essential role

of nurses, midwives, and lactation consultants in providing breastfeeding education and individualized support.

Keywords: breastfeeding methods, breastfeeding positions, infant attachment, maternal comfort, breastfeeding support, lactation, nursing practice.

INTRODUCTION:

Breastfeeding is widely acknowledged as the gold standard for infant nutrition and plays a critical role in promoting maternal and child health. Breast milk provides a complete source of nutrition during early infancy and contains bioactive components that protect against infectious diseases, support cognitive development, and contribute to long-term health outcomes (Victora et al., 2016). The benefits of breastfeeding extend beyond infancy. Research demonstrates that breastfed infants experience lower rates of respiratory infections, gastrointestinal illnesses, obesity, diabetes, and sudden infant death syndrome (Victora et al., 2016). Mothers who breastfeed benefit from accelerated postpartum recovery and reduced risks of breast cancer, ovarian cancer, and cardiovascular disease (WHO, 2023). Among the most common barriers to successful breastfeeding are poor infant positioning, ineffective attachment, nipple pain, inadequate milk transfer, breast engorgement, and maternal discomfort (McFadden et al., 2019). Studies have consistently identified improper breastfeeding technique as a significant contributor to breastfeeding failure and premature discontinuation (Riordan & Wambach, 2021). Consequently, healthcare providers increasingly emphasize breastfeeding education focused on positioning and attachment as essential components of breastfeeding support. Choosing the most suitable breastfeeding approach depends on several factors, including the mother's physical characteristics, the infant's developmental needs, the type of birth, previous breastfeeding experience, and specific medical conditions such as prematurity or gastroesophageal reflux. (Lawrence & Lawrence, 2022). This review of the literature explores existing research on different breastfeeding techniques and assesses their role in supporting positive breastfeeding outcomes. The review further explores factors influencing position selection and discusses implications for nursing and lactation practice.

OBJECTIVES:

The primary objective of this literature review is to examine and synthesize existing evidence regarding various breastfeeding methods and their effectiveness in promoting successful breastfeeding outcomes. The review aims to provide a comprehensive understanding of commonly used breastfeeding positions and techniques, including their benefits, limitations, and clinical applications. This review seeks to evaluate the effectiveness of different breastfeeding methods in facilitating proper infant attachment, efficient milk transfer, maternal comfort, and sustained breastfeeding practices. It also aims to explore the factors that influence the selection of breastfeeding positions, including maternal characteristics, infant developmental status, mode of delivery, and specific clinical conditions. The review aims to identify gaps in the existing literature and highlight areas requiring further research to strengthen evidence-based breastfeeding practices and improve maternal and child health outcomes.

METHODOLOGY:

This study employed a narrative literature review design to examine and synthesize existing evidence on various breastfeeding methods and their effectiveness in promoting successful breastfeeding outcomes. A comprehensive search of relevant literature was conducted using electronic databases, including pubmed, google scholar, cochrane library, and sciencedirect. Additional information was obtained from publications and guidelines issued by the World Health Organization and United Nations Children's Fund. The selected literature was critically reviewed and organized according to major themes, including the characteristics of different breastfeeding positions, factors influencing position selection, breastfeeding outcomes, maternal and infant benefits, and implications for nursing and lactation practice.

INCLUSION AND EXCLUSION CRITERIA

To ensure methodological rigor and relevance, specific inclusion and exclusion criteria were applied during the selection of literature for this review

Inclusion criteria

The inclusion criteria for this literature review were carefully defined to ensure that only relevant, high-quality, and evidence-based studies were selected. The review included peer-reviewed journal articles, systematic reviews, meta-analyses, randomized controlled trials, observational studies, and evidence-based clinical guidelines related to breastfeeding methods and positioning techniques. Studies were included if they specifically examined at least one breastfeeding position, such as the cradle hold, cross-cradle hold, football hold, side-lying position, laid-back breastfeeding (biological nurturing), upright or koala hold, or techniques used for breastfeeding twins and multiples. Literature was included if it focused on outcomes such as breastfeeding success, maternal comfort, infant attachment, milk transfer efficiency, breastfeeding duration, or breastfeeding-related complications. Only studies published in the English language and available in full text were included to ensure clarity, accuracy, and ease of analysis. In addition, authoritative publications and guidelines from recognized organizations such as the World Health Organization and UNICEF were also included to support evidence-based practice and strengthen the validity of the review.

Exclusion criteria

The exclusion criteria for this literature review were established to ensure that only relevant, high-quality, and methodologically appropriate studies were included. Studies were excluded if they did not specifically address breastfeeding methods or positioning techniques, even if they discussed breastfeeding in general terms. Articles focusing solely on formula feeding, bottle feeding, or general infant nutrition without comparison to breastfeeding positions were not considered relevant to the objectives of this review. Non-peer-reviewed sources such as opinion articles, editorials, and informal blog content were excluded due to limited scientific validity. Duplicate publications and studies with insufficient or unclear methodological information were also excluded to maintain the quality and reliability of the review. Additionally, studies published in languages other than English were excluded due to translation constraints. Studies with a primary focus on unrelated medical conditions without relevance to breastfeeding positioning were also excluded.

CONCEPTUAL FRAMEWORK OF BREASTFEEDING METHODS:

Successful breastfeeding is a dynamic interaction involving physiological, behavioral, and environmental factors. Effective breastfeeding depends on three fundamental components: proper maternal positioning, correct infant positioning, and successful attachment or latch (WHO, 2023). These components work together to facilitate efficient milk transfer and ensure a positive breastfeeding experience.

Maternal positioning plays a crucial role in breastfeeding success. Mothers who are comfortable and well supported during feeding are more likely to sustain breastfeeding for longer periods and report higher levels of satisfaction (Kent et al., 2011). Physical discomfort, particularly neck, shoulder, and back pain, has been associated with shorter breastfeeding duration and reduced maternal confidence. Therefore, breastfeeding positions must accommodate maternal comfort while promoting effective infant attachment.

Infant positioning is equally important. Effective positioning requires alignment of the infant's head, neck, and spine while maintaining close body contact with the mother. Research suggests that infants who are correctly positioned demonstrate improved coordination of sucking, swallowing, and breathing, resulting in more efficient feeding and enhanced weight gain (Victora et al., 2016).

Poor positioning often contributes to breastfeeding difficulties, including inadequate milk transfer and nipple trauma. According to UNICEF (2023), effective attachment is characterized by a wide-open mouth, outwardly flanged lips, chin contact with the breast, and visible swallowing. Poor attachment is a leading cause of sore nipples, breast engorgement, blocked ducts, mastitis, and poor infant growth (Lawrence & Lawrence, 2021).

The literature consistently demonstrates that interventions focused on improving positioning and attachment significantly enhance breastfeeding outcomes. McFadden et al. (2022) reported that breastfeeding education and support programs substantially increased rates of exclusive breastfeeding and reduced breastfeeding-related complications.

CRADLE HOLD METHOD:

The cradle hold remains one of the most widely recognized breastfeeding positions worldwide. In this method, the infant lies horizontally across the mother's chest with the head resting in the crook of the arm corresponding to the feeding breast. This position is frequently illustrated in breastfeeding education resources and is widely regarded as the conventional breastfeeding technique. (Lawrence & Lawrence, 2022).

The literature identifies several advantages associated with the cradle hold. This breastfeeding position encourages close body contact and direct visual interaction between the mother and infant, which can help foster emotional connection and strengthen attachment. (Riordan & Wambach, 2022). Older infants who have developed adequate head and neck control often feed effectively in this position, making it a practical option for established breastfeeding relationships. Several studies suggest that the cradle hold promotes positive psychosocial interactions.

Victora et al. (2016) noted that breastfeeding interactions involving direct visual engagement contribute to infant cognitive and emotional development. Despite these advantages, the cradle hold presents certain limitations. Newborns often require greater head and neck support than the position provides. Consequently, first-time mothers may struggle to achieve optimal latch and positioning. Lawrence and Lawrence (2021) observed that inadequate support in the cradle hold may increase the likelihood of shallow attachment and nipple discomfort.

Mothers recovering from cesarean delivery frequently report discomfort due to pressure on the abdominal incision. Current evidence suggests that while the cradle hold remains a useful breastfeeding position, it may be most appropriate after breastfeeding has been successfully established and infants have developed improved motor control.

CROSS-CRADLE HOLD METHOD:

The cross-cradle hold is widely recommended by lactation consultants as an effective breastfeeding position during the early postpartum period. Unlike the traditional cradle hold, the infant is supported by the arm opposite the feeding breast, allowing greater control of head and neck positioning (Riordan & Wambach, 2022).

Research indicates that the cross-cradle hold facilitates improved latch and attachment, particularly among newborns and premature infants. Meier et al. (2013) reported that preterm infants demonstrated more effective feeding behaviors when additional head support was provided. The position enables mothers to guide the infant toward the breast and correct positioning errors more easily.

The literature also highlights the role of the cross-cradle hold in reducing nipple trauma. McFadden et al. (2022) found that mothers who received instruction in this position during the immediate postpartum period reported fewer breastfeeding complications and greater breastfeeding confidence.

However, several limitations have been identified. Prolonged use of the cross-cradle hold may contribute to maternal arm, wrist, and shoulder fatigue because the mother must continuously support

the infant. Many women require pillows or breastfeeding cushions to maintain comfort during longer feeding sessions (Lawrence & Lawrence, 2021).

FOOTBALL HOLD (CLUTCH HOLD):

The football hold has gained substantial attention within lactation research because of its versatility and clinical utility. In this position, the infant is placed under the mother's arm on the same side as the feeding breast, with the body extending toward the mother's back.

Numerous studies have identified the football hold as particularly beneficial following cesarean delivery. WHO (2023) recommends this position because it avoids pressure on the surgical incision and promotes maternal comfort during recovery. Women with larger breasts often find that this technique provides better visibility of the infant and allows for more comfortable and effective positioning during breastfeeding. (Lawrence & Lawrence, 2021).

The football hold has also been identified as particularly useful for premature infants, as it enhances support and feeding control. (Meier et al. 2013) further noted that improved stabilization of the head and neck contributes to more efficient feeding in preterm infants. The position also allows healthcare providers to observe attachment and provide real-time feedback.

For mothers of twins, the football hold offers additional advantages. Breastfeeding twins simultaneously in the double football hold has been linked to enhanced feeding effectiveness and increased maternal comfort and satisfaction. (Riordan & Wambach, 2022). Despite its benefits, the football hold often requires multiple pillows and support devices. Some mothers describe the position as awkward initially, and larger infants may become difficult to position comfortably as they grow.

SIDE-LYING POSITION:

The side-lying position involves both mother and infant lying on their sides facing one another. This method is commonly used during nighttime feedings and postpartum recovery. The literature consistently identifies maternal comfort as the primary advantage of side-lying breastfeeding. Riordan and Wambach (2022) reported that mothers experiencing postpartum fatigue frequently prefer this position because it allows rest during feeding. Women recovering from cesarean delivery similarly benefit from reduced abdominal pressure.

Research also suggests that side-lying breastfeeding reduces musculoskeletal strain. Ezeukwu et al. (2020) found that breastfeeding positions differ significantly in terms of biomechanical stress and muscle activation. Positions that minimize postural strain may support longer breastfeeding duration.

Healthcare providers may find it difficult to assess latch quality when mother and infant are lying down. Safety concerns have also been raised regarding accidental sleep during feeding. The American Academy of Pediatrics (2022) emphasizes adherence to safe sleep guidelines and recommends returning infants to separate sleep surfaces after feeding. Although the side-lying position offers significant comfort benefits, appropriate education and safety precautions are essential.

LAID-BACK BREASTFEEDING (BIOLOGICAL NURTURING):

Laid-back breastfeeding, introduced by Colson (2010), is based on the concept of biological nurturing. The mother reclines comfortably while the infant lies prone on her chest and uses innate feeding reflexes to locate and attach to the breast.

Research examining biological nurturing has produced promising findings.

Yuan et al. (2021) conducted a meta-analysis demonstrating that laid-back breastfeeding significantly reduced nipple pain and breastfeeding-related discomfort. The position appears to facilitate deeper attachment and more effective milk transfer.

The literature also highlights the importance of skin-to-skin contact in laid-back breastfeeding. Early skin-to-skin interaction promotes thermoregulation, infant stabilization, and breastfeeding initiation (WHO, 2023). Biological nurturing maximizes these benefits by encouraging uninterrupted contact.

Several authors suggest that laid-back breastfeeding aligns closely with natural infant feeding behaviors. By utilizing gravity and neonatal reflexes, the position reduces the need for active positioning and manipulation by the mother (Riordan & Wambach, 2022). Despite these advantages, adoption remains limited in some healthcare settings due to insufficient professional training and lack of familiarity with the technique.

UPRIGHT OR KOALA HOLD:

The upright or koala hold has emerged as a valuable alternative breastfeeding position for infants experiencing feeding challenges. In this position, the infant sits upright facing the mother while straddling the mother's thigh or hip.

The literature suggests several physiological benefits associated with upright breastfeeding. Lightdale and Gremse (2013) reported that maintaining infants in an upright posture may reduce symptoms of gastroesophageal reflux by utilizing gravity to minimize regurgitation. Consequently, lactation consultants frequently recommend the koala hold for infants with reflux-related feeding difficulties.

Research also indicates potential benefits for infants with tongue-tie and oral anatomical variations. Lawrence and Lawrence (2021) observed that upright positioning may facilitate deeper latch and improved oral motor function.

Furthermore, the koala hold supports respiratory function by promoting airway patency and facilitating coordination of sucking, swallowing, and breathing (Riordan & Wambach, 2022). These characteristics make the position particularly useful for infants with mild respiratory difficulties. Young newborns often lack sufficient head and trunk control to maintain an upright posture safely. Additionally, empirical research specifically examining the koala hold remains limited compared with more traditional positions.

BREASTFEEDING TWINS AND MULTIPLES:

Breastfeeding twins and higher-order multiples presents unique challenges that necessitate specialized feeding techniques. Although concerns regarding milk supply are common, evidence indicates that mothers can successfully produce sufficient milk through frequent and effective breast stimulation (Lawrence & Lawrence, 2021).

Simultaneous breastfeeding has received considerable attention in the literature because of its practical and physiological advantages.

The double football hold is the most frequently recommended position for twins. This technique provides excellent head and neck support while facilitating observation of both infants. Meier et al. (2013) noted particular benefits for premature or low-birth-weight infants. The cradle-football combination offers additional flexibility and allows individualized support for infants with differing feeding abilities. Mothers often transition among multiple positions as infants grow and feeding needs change.

Research consistently demonstrates that successful breastfeeding of multiples depends heavily on professional support. McFadden et al. (2022) found that early lactation counseling significantly improved breastfeeding initiation, exclusivity, and duration among mothers of twins. Despite its benefits, breastfeeding multiples remains associated with increased maternal fatigue, positioning challenges, and psychological stress. Comprehensive support from healthcare providers and family members is therefore essential.

FACTORS INFLUENCING BREASTFEEDING METHODS:

The literature identifies numerous factors that influence breastfeeding position selection. Maternal comfort consistently emerges as one of the strongest determinants. Women naturally gravitate toward positions that minimize pain and physical strain (Kent et al., 2011).

Infant age also influences position preference. Newborns typically require greater support, making cross-cradle and football holds particularly useful. As infants mature and gain motor control, cradle and upright positions become increasingly practical (Lawrence & Lawrence, 2021).

Mode of delivery represents another significant factor. After a cesarean delivery, many women prefer breastfeeding positions that minimize pressure on the abdomen, including the football hold and side-lying position. (WHO, 2023). Clinical conditions including prematurity, reflux, tongue-tie, respiratory disorders, and breastfeeding complications may necessitate specialized positioning strategies. Furthermore, cultural beliefs, family traditions, and access to breastfeeding education influence maternal preferences and practices (UNICEF, 2023).

Clinical Implications for Nursing Practice

The literature consistently highlights the essential role of nurses, midwives, and lactation consultants in supporting breastfeeding mothers. Effective breastfeeding education should include assessment of positioning, attachment, milk transfer, and maternal comfort. McFadden et al. (2022) demonstrated that structured breastfeeding support programs significantly improve exclusive breastfeeding rates. Healthcare providers should therefore teach multiple breastfeeding positions rather than promoting a single technique. Individualized assessment is particularly important because mothers and infants differ substantially in their physical characteristics and feeding needs. Nurses should encourage mothers to experiment with various positions and adapt techniques as circumstances change. Healthcare professionals must address psychological factors influencing breastfeeding success. Emotional support, reassurance, and confidence-building interventions are associated with improved breastfeeding outcomes and greater maternal satisfaction.

DISCUSSION:

The findings of this literature review demonstrate that breastfeeding success is influenced not only by the decision to breastfeed but also by the breastfeeding method employed and the ability of the mother and infant to achieve effective positioning and attachment. Across the reviewed literature, there is broad consensus that proper breastfeeding techniques contribute significantly to successful milk transfer, maternal comfort, infant growth, and the continuation of exclusive breastfeeding practices. Consistent with recommendations from the World Health Organization (WHO, 2023) and UNICEF (2023), breastfeeding positions should be individualized according to maternal and infant needs rather than applying a single universal approach. Research shows that maternal comfort plays a key role in successful breastfeeding. Consistent findings suggest that physical discomfort, muscle strain, and nipple pain are major factors contributing to early cessation of breastfeeding. (Kent et al., 2011; Riordan & Wambach, 2022).

Different breastfeeding positions provide varying levels of physical support and comfort. For example, the side-lying position and laid-back breastfeeding method appear particularly beneficial for mothers recovering from childbirth because they reduce physical strain and allow periods of rest during feeding. Similarly, mothers who have undergone cesarean delivery often benefit from positions such as the football hold because it minimizes pressure on abdominal incisions and facilitates comfortable breastfeeding during recovery (WHO, 2023). These findings emphasize the importance of assessing maternal comfort when recommending breastfeeding positions.

A key finding in the literature is the link between breastfeeding position and successful infant latch and attachment. Proper attachment is essential for adequate milk transfer and prevention of breastfeeding complications. Research consistently demonstrates that poor positioning contributes to shallow latch, nipple trauma, breast engorgement, blocked milk ducts, and mastitis (Lawrence & Lawrence, 2021).

Among the various breastfeeding methods reviewed, the cross-cradle hold appears particularly effective during the early postpartum period because it allows greater control of infant head positioning and facilitates deep attachment. Studies involving first-time mothers and premature infants have shown that enhanced head and neck support provided by the cross-cradle hold improves feeding effectiveness and reduces nipple pain (Meier et al., 2013; McFadden et al., 2022). These findings support the frequent recommendation of this position by lactation consultants and breastfeeding educators.

The cradle hold remains one of the most commonly practiced breastfeeding positions globally. However, the literature suggests that its effectiveness varies depending on infant age and breastfeeding experience. Although the cradle hold promotes mother–infant bonding through skin-to-skin contact and eye contact, it may not provide sufficient support for newborns who have not yet developed adequate head and neck control (Riordan & Wambach, 2022). This finding highlights the importance of matching breastfeeding techniques to developmental stages rather than assuming all positions are equally appropriate throughout infancy.

The football hold emerged as one of the most versatile breastfeeding positions identified in the literature. Evidence indicates that this method is particularly beneficial for mothers recovering from cesarean birth, women with large breasts, mothers of twins, and infants requiring additional support during feeding (WHO, 2023; Meier et al., 2013). The improved visibility offered by the football hold allows mothers and healthcare providers to assess latch quality more effectively. Furthermore, studies involving premature infants suggest that the enhanced support provided by this position contributes to improved feeding performance and breastfeeding outcomes (Meier et al., 2013). Nevertheless, several authors acknowledge that the football hold often requires positioning aids such as pillows and may initially feel unfamiliar to mothers. Therefore, professional guidance and practical demonstrations remain important for successful implementation.

Another important finding concerns the growing evidence supporting laid-back breastfeeding, also known as biological nurturing. This approach differs from traditional breastfeeding instruction by encouraging mothers to recline and allow infants to utilize innate feeding reflexes to self-attach to the breast. Yuan et al. (2021) demonstrated that laid-back breastfeeding significantly reduces nipple pain and breastfeeding-related discomfort. These findings suggest that biological nurturing may offer an effective strategy for preventing common breastfeeding problems while promoting natural infant feeding behaviors. Furthermore, the enhanced skin-to-skin contact associated with this position may facilitate maternal-infant bonding and support successful breastfeeding initiation. Despite these benefits, the literature indicates that implementation remains limited due to insufficient awareness and training among healthcare professionals.

The upright or koala hold represents a relatively underexplored but clinically valuable breastfeeding position. Available evidence suggests that this technique can be especially helpful for infants affected by gastroesophageal reflux, tongue-tie, oral motor impairments, or mild breathing difficulties. (Lightdale & Gremse, 2013; Lawrence & Lawrence, 2021). By maintaining the infant in an upright posture, gravity assists swallowing and reduces regurgitation episodes. However, compared with traditional breastfeeding positions, relatively few empirical studies have specifically examined the effectiveness of the koala hold. Much of the available evidence originates from clinical observations and expert recommendations rather than randomized controlled trials. Consequently, further research is needed to establish stronger evidence regarding its effectiveness across different infant populations.

The literature concerning breastfeeding twins and multiples highlights the importance of specialized positioning techniques and comprehensive professional support. Simultaneous breastfeeding methods, particularly the double football hold, have been associated with improved efficiency, increased maternal confidence, and enhanced milk production through simultaneous breast stimulation (Riordan & Wambach, 2022). These results reinforce the physiological concept that milk production is regulated by the balance between infant demand and maternal supply. However, breastfeeding multiples is frequently associated with increased maternal fatigue, positioning challenges, and concerns regarding milk supply. Studies consistently emphasize the critical role of lactation consultants and nursing support in helping mothers develop effective breastfeeding routines and overcome breastfeeding-related challenges (McFadden et al., 2022).

The review also highlights the multifactorial nature of breastfeeding position selection. Maternal characteristics, including breast anatomy, physical comfort, mode of delivery, and previous breastfeeding experience, influence the suitability of different positions. Similarly, infant-related factors such as age, developmental status, prematurity, feeding ability, and medical conditions contribute to position selection (Lawrence & Lawrence, 2021). These findings reinforce the concept that breastfeeding support should be individualized rather than standardized. Healthcare providers must assess the unique circumstances of each mother–infant dyad and provide personalized recommendations that accommodate their specific needs and preferences.

From a nursing perspective, the evidence strongly supports the importance of breastfeeding education and hands-on support. Structured breastfeeding interventions that include instruction on positioning and attachment have consistently been associated with higher rates of exclusive breastfeeding and longer breastfeeding duration (McFadden et al., 2022). Nurses, midwives, and lactation consultants play a pivotal role in identifying breastfeeding difficulties, correcting positioning errors, and providing emotional encouragement. Research indicates that mothers who receive adequate breastfeeding support tend to experience higher confidence, encounter fewer difficulties, and report more satisfying breastfeeding outcomes.

Although breastfeeding research has progressed considerably, important gaps in knowledge still exist. Comparative studies directly evaluating the effectiveness of different breastfeeding positions are relatively limited. Most available research focuses on individual positions or specific clinical populations rather than providing comprehensive comparisons across breastfeeding methods (Colson et al., 2010; Milinco et al., 2020). Furthermore, there is a lack of long-term studies examining how breastfeeding positions influence breastfeeding duration, infant growth outcomes, maternal satisfaction, and breastfeeding self-efficacy (Rollins et al., 2016; Victora et al., 2016). Additional research is also needed to evaluate breastfeeding interventions among mothers with disabilities, obese mothers, and culturally diverse populations (World Health Organization (WHO), 2023). Emerging technologies, including telehealth and digital breastfeeding education platforms, may offer promising opportunities for improving breastfeeding support and warrant further investigation (Demirci et al., 2019).

The evidence reviewed suggests that no single breastfeeding position can be considered universally superior. Rather, successful breastfeeding depends on selecting and adapting breastfeeding methods according to maternal comfort, infant needs, and clinical circumstances (American Academy of Pediatrics, 2022; Colson et al., 2010). The findings support a patient-centered approach to breastfeeding care in which mothers are encouraged to explore multiple breastfeeding positions and receive individualized guidance from healthcare professionals. Such an approach has the potential to improve breastfeeding outcomes, reduce breastfeeding-related complications, and promote the health and well-being of both mothers and infants.

CONCLUSION:

Breastfeeding remains the most effective and evidence-based method of infant feeding, offering substantial nutritional, immunological, developmental, psychological, and economic benefits for both infants and mothers. This literature review examined various breastfeeding methods, including the cradle hold, cross-cradle hold, football hold, side-lying position, laid-back breastfeeding, upright or koala hold, and specialized techniques for breastfeeding twins and multiples.

The evidence indicates that each breastfeeding position has distinct advantages and limitations, with effectiveness varying according to maternal comfort, infant developmental stage, health status, and specific clinical circumstances. The review highlights that proper positioning and attachment are fundamental to successful breastfeeding, as they facilitate efficient milk transfer, reduce breastfeeding-related complications, and enhance maternal satisfaction.

Positions such as the cross-cradle and football hold appear particularly beneficial during the early postpartum period and for infants requiring additional support, while side-lying and laid-back

breastfeeding promote maternal comfort and recovery. Healthcare professionals, particularly nurses, midwives, and lactation consultants, play a critical role in providing education, practical guidance, and ongoing support to help mothers develop effective breastfeeding skills and confidence.

Despite the growing body of evidence, gaps remain in the literature regarding long-term outcomes associated with different breastfeeding positions and their impact on breastfeeding duration, maternal comfort, and infant growth. Future research should focus on comparative studies, culturally sensitive breastfeeding interventions, and innovative educational approaches that enhance breastfeeding support across diverse populations. Ultimately, a patient-centered and evidence-based approach to breastfeeding education and practice can contribute significantly to improving breastfeeding success, maternal well-being, and child health outcomes worldwide.

Future Directions for Research

Although considerable research has examined breastfeeding techniques, important gaps remain. Comparative studies evaluating long-term breastfeeding outcomes associated with different positions are limited. Further investigation is needed to determine whether specific positions influence breastfeeding duration, infant growth, or maternal satisfaction. Biomechanical research examining maternal posture and musculoskeletal health represents another promising area of inquiry. Further studies are required to better understand breastfeeding practices among premature infants, infants with feeding difficulties, and mothers with physical disabilities.
